DBS_READ

DB_READ and DBS_READ actions

Function

Reading of one or several row of the table.

Declaration

```
DB_READ handleIdent_Int, rowIdent, retCodeIdent_Int [WHERE
strExpression_Str [BINDIN varIdent1, varIdent2, ... ]] [ORAHINT
hintIdent_Str]

 DB_READ handleIdent_Int, rowIdent, retCodeIdent_Int [WHERE
strExpression_Str [BINDIN structRowIdent ]] [ORAHINT hintIdent_Str]

 DBS_READ dbObjIdent, rowIdent, retCodeIdent_Int [WHERE strExpression_Str
[BINDIN varIdent1, varIdent2, ... ]] [TRANS transHandle_Int] [ORAHINT
hintIdent_Str]

 DBS_READ dbObjIdent, rowIdent, retCodeIdent_Int [WHERE strExpression_Str
[BINDIN structRowIdent ]] [TRANS transHandle_Int] [ORAHINT hintIdent_Str]
```

or

```
DB_READ handleIdent_Int, localStructIdent, retCodeIdent_Int, maxRows_Int
[WHERE strExpression_Str [BINDIN varIdent1, varIdent2, ... ]] [ORAHINT
hintIdent_Str]

 DB_READ handleIdent_Int, localStructIdent, retCodeIdent_Int, maxRows_Int
[WHERE strExpression_Str [BINDIN structRowIdent ]] [ORAHINT hintIdent_Str]

 DBS_READ dbObjIdent, localStructIdent,retCodeIdent_Int, maxRows_Int
[WHERE strExpression_Str [BINDIN varIdent1, varIdent2, ... ]] [TRANS
transHandle_Int] [ORAHINT hintIdent_Str]

 DBS_READ dbObjIdent, localStructIdent,retCodeIdent_Int, maxRows_Int
[WHERE strExpression_Str [BINDIN structRowIdent ]] [TRANS transHandle_Int]
[ORAHINT hintIdent_Str]
```

Parameters

handleIdent_Int	in	Identifier (handle) of *Int* type of the connection with a table (DB_CONNECT).
dbObjIdent	in	A reference to an object of Table type
rowIdent	in / out	Whole local structure identifier.
retCodeIdent_Int	out	Return code identifier.
localStructIdent	out	Whole local structure identifier.

maxRows_Int	in	Identifier of *Int* type. Maximal number of read rows.
strExpression_Str	in	Expression of *String* type, that defines a table row (rows) which is to be read. The parameter can also contains a sorting condition (e.g. "*ID<100 ORDER BY Name*"). If the expression is parameterized, the keyword **BINDIN** and the values of parameters (*structRowIdent* or *varIdent1*, *varIdent2*, ...) are mandatory.
varIdent1, varIdent2, ...	in	List of objects, constants or local variables, which will specify the values of parameters of parameterized SQL expression *strExpression_Str*.
structRowIdent	in	Reference to a row of local variable of *Record* type or to a row of structured variable. The row's values will specify the values of parameters of parameterized SQL expression *strExpression_Str*.
transHandle_Int	in	Identifier of the *Connection* to the database.
hintIdent_Str	in	Expression of *String* type that defines Oracle SQL hint. It is used as an instruction for the performance optimizer of SQL command. The value is used without the opening and terminating characters /*+ *<orahint>* */. The example is mentioned here.

Return code

The value of the parameter *transHandle_Int*. See the table of error codes. It is possible to get extended error information.

Description

The **WHERE** clause for SQL command **SELECT**, which executes the selection from a table, is defined by either the value of *strExpression_Str*, or, if this value is not defined, the values from the defined (valid) key items (those items which were set as key when configuring the object Table) in the first row of structure (*rowIdent* or *localStructIdent[1]*). These values must be set before executing **DB_READ** (**DBS_READ**).

It follows that **WHERE** clause is not a part of SQL command **SELECT**, if the value of *strExpression_Str* is not defined and

- there are not the key items (the items specified as key ones when configuring the object *Tabuka*),
- or there is not defined (valid) any value of the key items,
- or the structure has a null size (for *localStructIdent*).

The first form of the action declaration allows to read just one row of a table to one line of a structure.

If more rows than one meet the selection condition during the selection, the action **DB_READ (DBS_READ)** is to be read the first row. If no row meet the condition, the action will send back the error by means of *retCodeIdent_Int*. Structure type (`rowIdent`) must be equal to the table type.

The second form of the declaration allows to read one or more rows from a table. Value of the parameter *maxRows* determines the maximal number of rows. If this value is set to -1, then the system will attempt to read all rows matching the specified condition. Maximum number of rows is limited by a Database configuration parameter Maximum returned rows. Exceeding this number, the first Maximum returned rows will be stored in local structure *localStructIdent* and *retCodeIdent_Int* will be set to _ERR_DATABASE_ROWS_LIMIT.
If the value of *maxRows* is greater than Maximum returned rows, at the most Maximum returned rows will be read. If more rows are available, *retCodeIdent_Int* will be set to error code _ERR_DATABASE_ROWS_LIMIT.

If the value of the parameter *maxRows* is set to -2, the system at first detects how many rows meet given condition. If the number of rows is 0 or it is more than Maximum returned rows, the system will not read any rows, or reads all detected rows otherwise. For optimization reasons, this method may be faster than the method for maxRows=-1. Number of rows is detected by the SQL command "*SELECT COUNT(*) FROM table_name [WHERE where_condition]*". If the condition *StrExpression_Str* is defined, it is also tested for the presence of an *ORDER BY* clause. If the result is positive, the clause is removed along with all following text. It is removed because when detecting the number of rows e.g. Sybase doesn't accept "*SELECT COUNT(*) FROM aaaa WHERE bbbb = cccc ORDER BY dddd*" and returns the error ***Function or column reference to 'dddd' in the select list must also appear in a GROUP BY***.

The parameter *localStructIdent* must be the name of a local structure of the corresponding type (i.e. with the same Structure type that is used in the configuration of the object *dbObjIdent* of Table type). If you want to be sure that the result will not be controlled by **WHERE** clause, which consists of the key items, you should change the size of local structure to 0 (zero) before calling DB_READ (DBS_READ).

After reading rows from the database, they are assigned to the local variable *localStructIdent*. Its size may be changed in case of need (**REDIM**). If no row meet the selection condition, the action is to be terminated successfully (*retCodeIdent_Int* = *_ERR_NO_ERROR*) and the structure size *localStructIdent* is to be changed to 0.

The advantage of using the action **DBS_READ** is omitting the table opening and closing (shorter code).

For D2000 v5.00: an disadvantage of the action **DBS_READ** is in speed. Each **DBS_READ** call results in necessity to open and close the database in DBManager - it can be a time-consuming operation and it is a comparatively nonstandard method in term of databases.
The need to open and close the database may be avoided in the scope of transaction processing so that the command is followed by the parameter

```
TRANS
```

.

For D2000 v6.00 and higher: DBManager optimization (connection recycling, predefined connections) causes the action **DBS_READ** to execute as fast as the action **DB_READ** and moreover time is saved omitting the execution of the action **DB_CONNECT**.

Example

Work with a database table (actions DB_ ...).
