

# Complete synchronization of databases in a redundant system

## D2000 CfgSynchro - complete database synchronization in a redundant system

This way of synchronization is identical with [Complete synchronization of configuration databases](#), however, objects with same UIDs but different HOBJs (unique identifier of an object within one configuration database) are included in the group of objects to be copied. This condition must be met for configuration databases of those processes [D2000 Server](#), which form the redundant group.

The initial setting of copying is the same as for [Complete synchronization of configuration databases](#).
