

# Resource

**Resource** object is a container for files and directories which an application needs for its function. The physical contents of files and directories is stored in the configuration of **Resource** object in the configuration database. The content of **Resource** is, depending on a configuration, synchronized automatically (mirrored) into an application directory of the client processes. A path to the mirrored content may be located by calling the ESL function [%GetResourcePath](#).

The application may stored the content of **Resource** (even source) explicitly by ESL function [%SaveResourceAs](#).

The excel templates, reports, java libraries and utilities represent the application usage of **Resource** objects.

The size of one object, i.e. sum of files in *resource* is limited to 20MiB.
