Calendars

A calendar is an object with definitions of day types for every day in a year. The calendars are used to define time channels, but they can also be used as independent objects (e.g. in expressions of eval tags). The value of the object of **Calendar** type is a value of the current day type:

- 1 - workday,
- 2 - Saturday,
- 3 - Sunday,
- 4 - the object of **Day type** created by the system configurator as the first,
- 5 - the object of **Day type** created by the system configurator as the second, etc.
