

# Call-back procedures

Call-back procedures ensures the callbacks of **GrEditor** from import dll. They enable to create the graphic objects in the active pictures of **D2000 System** by decoding of import file. They are designed to suit to all future formats of D2000 System pictures. I.e. the import dll will work also in next versions of D2000 System. However, it will not be able to use new features of the import.

In the table, you can find the types of procedures:

Procedure	procType	Description
CreateObj	1	Creates a new graphic object.
ObjAction	2	Action with objects.
Set_string	3	Inserts a text into the particular parameter when creating the graphic object.
Set_boolean	4	Inserts a logical value into the particular parameter when creating the graphic object.
Set_integer	5	Inserts an integer value into the particular parameter when creating the graphic object.
Set_float	6	Inserts a real value into the particular parameter when creating the graphic object.
Set_integer2	7	Inserts two integer values into the particular parameter when creating the graphic object.
Set_float2	8	Inserts two real values text into the particular parameter when creating the graphic object.
ShowInfo	0	Shows the information about import.

You can find the list of parameters and some permitted values in the chapter that describes the interface for a compiler of **ADA** and **C** languages.

**Note:** The integer and real values are transformed into the internal representation of value of the influenced parameter.

## CreateObj

This procedure creates a graphic object or object that can be added to the other created. You can find more information in the chapter [Graphic object creating](#).

The function definition in compilers of "ADA" and "C":

```
type tCreateObj is access procedure (objType : integer);
void __stdcall (*CreateObj)(int)
```

## ObjAction

This procedure executes an action with the created object according to defined parameter.

The function definition in compilers of "ADA" and "C":

```
type tObjAction is access procedure (action : tObjAction :=closeObject);
void __stdcall (*ObjAction)(tObjAction)
```

The definition of parameter type in compilers of "ADA" and "C":

```
type tObjAction is (closeFigure, closeObject, closeGroup,closeAll);
```

## The parameters:

Parameter	objType	Description
closeFigure	0	Closes the position group of points of Polyline - changes the object to polygon.
closeObject	1	Closes the object creation (the object is closed automatically as soon as you start to create new object).
closeGroup	2	Closes the group of objects - closes the object creating and the last object of Group type.
closeAll	3	Closes all the semifinished objects - closes the object creating and all objects of Group type. The function with this parameter is called automatically when finishing the import.

## Set\_string

The procedure inserts a text to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_string is access procedure (param : integer; val:string);
void __stdcall (*Set_string)(int,char far *)
```

## Set\_boolean

---

This procedure inserts a logic value to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_boolean is access procedure (param : integer;val :boolean);
void __stdcall (*Set_boolean)(int,bool)
```

## Set\_integer

---

This procedure inserts an integer value to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_integer is access procedure (param : integer;val :integer);
void __stdcall (*Set_integer)(int,int)
```

## Set\_float

---

This procedure inserts a real value to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_float is access procedure (param : integer; val:long_float);
void __stdcall (*Set_float)(int,real)
```

## Set\_integer2

---

This procedure inserts two integer value to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_integer2 is access procedure (param : integer;val1,val2 : integer);
void __stdcall (>Set_integer2)(int,int,int)
```

## Set\_float2

---

This procedure inserts two real value to the parameter of created graphic object.

The definition of function type in the compilers of "ADA" and "C":

```
type tset_float2 is access procedure (param : integer;val1,val2 : long_float);
void __stdcall (*Set_float2)(int,real,real)
```

## ShowInfo

---

This procedure inserts a text to the information window which is opened during import.

The definition of function type in the compilers of "ADA" and "C":

```
type tShowInfo is access procedure (text : string);
void __stdcall (*ShowInfo)(char far *)
```
