

Extended error information

If an error occurs during the execution of a database transaction, the return code (the parameter *retCodeIdent_Int*) is equal to the constant `_ERR_TRANS_ERROR`. Extended error information is contained in the variable `_ERR_NR_TRANS_EX`. If the error cause is in calling an ODBC interface function, the function `%GetLastExtErrorCode` returns an error code obtained by calling `SQLError`, specific for the particular database (Sybase, Oracle, ...). The `%GetLastExtErrorMsg` function returns a text description of the error obtained by calling `SQLError`.
